

Most Important SQL Interview Question

What is DBMS?

A database management system (DBMS) is a program that controls creation, maintenance and use of a database. DBMS can be termed as file manager that manages data in a database rather than saving in the file systems.

What is RDBMS?

RDBMS stands for relational database management system. RDBMS store the data into collection of tables, which is related by common fields between the columns of the table. It also provides relational operators to manipulate the data stored in the tables.

Example: SQL server

What is SQL?

SQL stand for structured query language, and it is used to communicate with database. This is a standard language used to perform tasks such as retrieval, standard SQL commands are select.

What is Database?

Database is nothing but an organized form of data for easy access, storing, retrieval and managing of data. This is also known as structured form of data which can be accessed in many ways.

Example: School Management Database,
Bank management database

What are tables and Fields?

A table is a set of data that are organized in a model with Columns and Rows. Columns can be categorized as vertical, and Rows are Horizontal. A table has specified number of column called fields but can have any number of rows which is called record.

Example:

Table: Employee.

Field: Emp id, Emp name, date of birth.

Data: 201457, David, 11/06/1980

What is a primary Key?

A primary key is a combination of fields which uniquely specify a row. This is a special kind of unique key, and it has

implicit NOT NULL constraint. It means, Primary key values cannot be null.

What is a unique key?

A unique key constraint uniquely identified each record in the database. This provides uniqueness for the column or set of columns.

A primary key constraints has automatic unique constraint defined on it. But not, in the case of unique key.

There can be many unique constraint defined per table, but only one primary key constraint defined per table.

What is a foreign key?

A foreign key is one table which can be related to the primary key of another table. Relationship needs to be created between two tables by referencing foreign key with the primary key of another table.

What is a join?

This is a keyword used to query data from more tables based on the fields of tables, Keys play a major role when JOINS are used.

What is Normalization?

Normalization is a process of minimizing redundancy and dependency by organizing fields and table of a database. The main aim

of Normalization is to add, delete or modify field that can be made in a single table.

What are all the different Normalization?

Database normalization can be easily understood with the help of a case study. The normal forms can be divided into 6 forms, and they are explained below:

- **First Normal form(1NF):**

This should remove all the duplicate columns from the table. Creation of tables for the related data and identification of unique columns.

- **Second Normal form(2NF):**

Meeting all requirements of the list normal form. Placing the subsets of data

in separate tables and creation of relationships between the tables using primary keys.

- **Third Normal Form (3NF):**

This should meet all requirements of 2NF. Removing the columns which are not dependent on primary key constraints.

- **Fourth Normal form(4NF):**

If no database table instance contains two or more, independent and multivalued data describing the relevant entity, then is in 4th Normal Form

.

- Fifth Normal form(5NF):

A table is in 5th normal form only if it is in 4thNF and it can't be decomposed into any number of smaller tables without loss of data.

- Sixth Normal form(6NF):

6th Normal form is not standardized, yet however, it is being discussed by database experts for some time. Hopefully, we would have a clear & standardized definition for 6th Normal form in the near future..

What are local and global variables and their difference?

- Local variables are the variables which can be used or exist inside the function. They are not known to other functions and those variables cannot be referred or used. Variables can be created whenever that function is called.
- Global variables are the variables which can be used or exist throughout the program. Same variable declared in the global can't be used in functions. Global variables can't be created whenever that function is called.

What is constraint?

Constraint can be used to specify the limit on the data type of table.

Constraint can be specified while creating or altering the table statement.

Sample of constraint are:

- NOT NULL
- CHECK
- DEFAULT
- UNIQUE
- PRIMARY KEY
- FOREIGN KEY

What is data Integrity?

Data integrity defines the accuracy and consistency of data stored in a database. It can also define integrity constraints to

enforce business rules on the data when it is entered into the application or database.

What is Data Warehouse?

Data warehouse is a central repository of data from multiple sources of information. Those data are consolidated, transformed and made available for the mining and online processing Warehouse data have a subset of data called Data Marts.

What is Denormalization?

Denormalization is a technique used to access the data from higher to lower normal forms of database. It is also

process of introducing redundancy into a table by incorporating data from the related tables.

What is a View?

A view is a virtual table which consists of a subset of data contained in a table. Views are not virtually present and it takes less space to store. View can have data of one or more tables combined, and it is depending on the relationship.

What is an index?

An index is performance tuning method of allowing faster retrieval of records from the table. An index creates an entry for

each value and it will be faster to retrieval data.

What is a relationship and what are they?

Database Relationship is defined as the connection between the tables in a database. There are various data base relationships, and they are as follows:

- One to One Relationship
- One to many Relationship
- Many to One Relationship
- Self-Referencing Relationship

What is query?

A database query is a code written in order to get the information back from the database. Query can be designed in such a

way that it matched with our expectation of the set. Simply, a question to the Database.

What is the difference between Delete and Truncate commands?

- DELETE commands is used to remove rows from the table, and WHERE clause can be used for conditional set of parameters. Commit and Rollback can be performed after delete statement.
- TRUNCATE removes all rows from the tables. TRUNCATE operation cannot be rolled back.

What is the difference between Cluster and Non-Cluster Index?

- Clustered index is used for easy retrieval of database by altering the way that the

records are stored. Database sorts out rows by the column which is set to be clustered index.

- A non-clustered index does not alter the way it was stored but creates a complete separate object within the table. It Point back to the original table rows after searching.

What is user defined functions?

User defined functions are the functions written to use that logic whenever required. It is nit necessary to write the same logic several times. Instead, function can be called or executed whenever needed.

What are the all types of user defined functions?

Three types of user defined functions are:

- Scalar Functions
- Inline Table valued Function
- Multi statement valued function.

Scalar returns until, variant defined the clause. Other two types return table as a return.

What are the all different types of collation sensitivity?

Following are different types of collation sensitivity-

- Case sensitivity – A and a and B and b.
- Accent sensitivity
- Kana sensitivity – Japanese Kana character
- Width sensitivity – single byte character and double byte character

What is Online Transaction Processing (OLTP)?

Online Transaction Processing manages transaction based applications which can be used for data entry, data retrieval and data processing. OLTP makes data management simple and efficient. Unlike OLTP systems is serving real-time transaction.

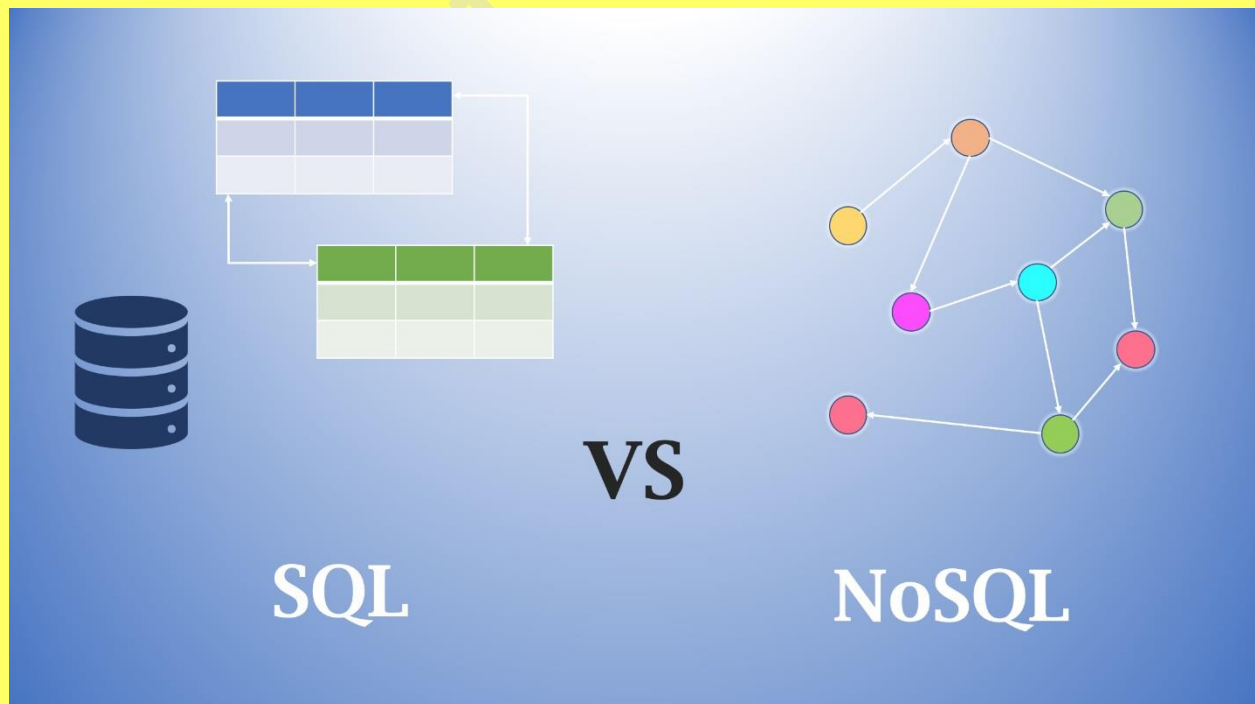

What is Microsoft (MS) SQL server?

- It is a software, developed by Microsoft, which is implemented from the specification of RDBMS.
- It is also an Object Relational Database management system (ORDBMS)
- It is a platform dependent
- It is both GUI and Command based software
- It supports SQL (SEQUEL) language which is an IBM product, non-procedural, common database and case insensitive language.

Usage of SQL server:

- To create databases.
- To maintain databases
- To analyze the data through SQL server analysis services (SSAS)
- To generate report through SQL server reporting services (SSRS)
- To carry out ETL operations through SQL server integration services (SSIS).

Difference Between SQL and NO SQL -

SQL

Relational Data Model

- Pros**
- › Easy to use and setup.
 - › Universal, compatible with many tools.
 - › Good at high-performance workloads.
 - › Good at structure data.

- Cons**
- › Time consuming to understand and design the structure of the database.
 - › Can be difficult to scale.

No SQL

Document Data Model

- Pros**
- › No investment to design model.
 - › Rapid development cycles.
 - › In general faster than SQL.
 - › Runs well on the cloud.

- Cons**
- › Unsuitable for interconnected data.
 - › Technology still maturing.
 - › Can have slower response time.
